

The Oklahoma Climatological Survey was established with its own budget and offices in the spring of 1980. The mission of the Survey is to provide a climatological archiving and information service to the State of Oklahoma. Although as many as 160 stations may appear in any one Summary, it may not be possible to list every station report received at the Survey as we plan to have the summaries in the mail before the middle of each month. If you would like information about a station that does appear, please feel free to contact the Climate Survey. If you would like to know more about the services we offer or our plans for the future, please let us hear from you. You can help us by contributing to our newspaper clipping file. If you see an article in your local newspaper dealing with some impact of climate on your community, please clip it and send it to us along with the name of the newspaper and the date the article appeared.

OKLAHOMA CLIMATE SUMMARY SEPTEMBER 1986

Most areas of the State received much above normal September rainfall. Exceptions were northwestern and southeastern Oklahoma. Climate Divisions 2, 3, 4, 5, and 7 recorded more than twice their normal precipitation totals (see Figure 1). Although monthly mean temperatures lay within 2 degrees of long-term expected values, daily temperatures tended to be below normal the first half of the month and above normal afterwards. Most stations recorded their lowest daily temperature in the first half of September and their highest after the 15th.

September began very wet. During the first week many stations Statewide experienced rain on several days (see Figure 2). On the 1st through the 3rd an upper level disturbance moving slowly across the State was associated with the precipitation. In Lawton, this rainfall prompted officials to curtail water rationing on the 2nd, 23 days ahead of the 1985 date. A stationary front settled over Oklahoma the second half of the week and delivered over 5 inches of rain in parts of Jackson County. In southeastern Oklahoma, Boggy Creek flooded crop and pasture lands in the Caney area and the National Weather Service issued flash flood watches for central and southeastern Oklahoma as other rivers approached flood stages. The abundant cloud cover and rain-cooled air during the first 7 days of September kept temperatures several degrees below normal. Oklahoma City's mean temperature for the week was 71 degrees compared to a 30-year average figure of 77.1 degrees.

Damaging storms accompanied a cold front through Oklahoma on the 10th. Strong southerly flow of very moist air ahead of the front and an upper level system moving toward the State served as the thunderstorm producing mechanisms. In Stephens County winds estimated at 70 mph blew roofs off buildings, Comanche reported 2.25 inches of rain and Duncan 2.61 inches. In Norman, a graduate student witnessed a rather unique event. The digital rainguage at the University's Meteorology Department briefly recorded precipitation falling at an

unprecedented rate of 12 inches per hour. Norman reported 1.96 inches for the day.

Oklahoma experienced more thunderstorms during the middle of the month. On the 14th, all but the northwest quarter of the State recorded precipitation. The greatest amount of rain, nearly 2 inches, fell over south central Oklahoma. During the next two days, an unstable air mass, low level moisture, and a stationary surface front generated additional storms. Bartlesville reported 5.60 inches for the 3 days which resulted in the closing of State Highway 60 near that city. Other northeastern Oklahoma 3-day rainfall reports included Pryor 2.63 inches and Wann 5.42 inches. On the 16th the National Weather Service issued a flash flood warning for Nowata, Washington, and Osage Counties. Street and low-land flooding, and small hail were reported in the area. Marlow and Duncan in Stephens County also reported hail on the 16th.

Several days of mostly rain-free weather ended on the 26th when a cold front and a strong upper level disturbance produced severe thunderstorms across the State. A tornado damaged barns and downed trees and power lines in Wagoner County, and weather observers reported funnel clouds south of Tulsa near Coweta, Bixby and Mounds.

The next several days provided some of the most spectacular weather of the year as a vigorous, nearly stationary upper level storm system (see related article) dumped over 20 inches of rain in north central Oklahoma and at least 5-10 inches in most areas of the State (see Figure 2). Although these rains continued into October, flooding occurred before month's end in Logan County where nearly 100 people were evacuated from their homes. In Skiatook, flood waters rose 15 feet over the Bird Creek banks forcing another 100 people to evacuate. The flooding struck some 40 homes and 15 businesses occupying 15 blocks. As the rains continued through the first few days of October hundreds of homes in the Tulsa area were evacuated as local rivers flooded. Although Tulsa recorded only 8.04 inches of rain in the several day period, both the Arkansas River and Bird Creek received large amounts of water draining from the adjacent areas of maximum precipitation.

Figure 1: The following nine graphs show the long-term mean and the 1986 September precipitation amounts for selected stations graphed along with the greatest amount of precipitation received in September prior to 1986.

METEOROLOGICAL CONDITIONS CONTRIBUTING TO THE OKLAHOMA
FLOOD OF LATE SEPTEMBER-EARLY OCTOBER 1986
Analysis by Tom Dunn

Portions of north central Oklahoma began to report rainfall as early as September 24 in response to a weak, southwestwardly moving cold front. The front was able to edge its way across only half of the State before losing strength and becoming stationary just to the northwest of Oklahoma City. This frontal boundary remained situated over northwestern Oklahoma for the following eight days, thus aiding in the development of shower and thunderstorm activity. In addition, the clockwise circulation around a large area of high pressure over the southeastern U.S. allowed warm and moist air from the Gulf of Mexico to overspread the State throughout the period. This helped to further destabilize the atmosphere. The high pressure cell extended well into the upper reaches of the atmosphere, where it began to inhibit the eastwardly movement of a developing upper-level low pressure area to the southwest of Oklahoma. The resulting position of the low pressure area was such that it created a preferred storm track extending from over Oklahoma northwestward into the upper Mississippi Valley region. Numerous upper-level storms and, eventually, the remnants of hurricane Paine migrated across Oklahoma along this storm track. This resulted in prolonged periods of intense rainfall over north central Oklahoma (see Figure 3). The rainfall persisted until the upper-level low pressure system began to push off slowly toward the northeast on the 3rd of October. A surface cold front accompanying the upper-level low swept through the panhandle region and finally exited the State during the afternoon of the 4th bringing an end to the widespread precipitation that gave rise to some of the worst flooding in Oklahoma history.

Figure 3: Rainfall for the last week of September through 7:00 a.m. October 3, 1986.

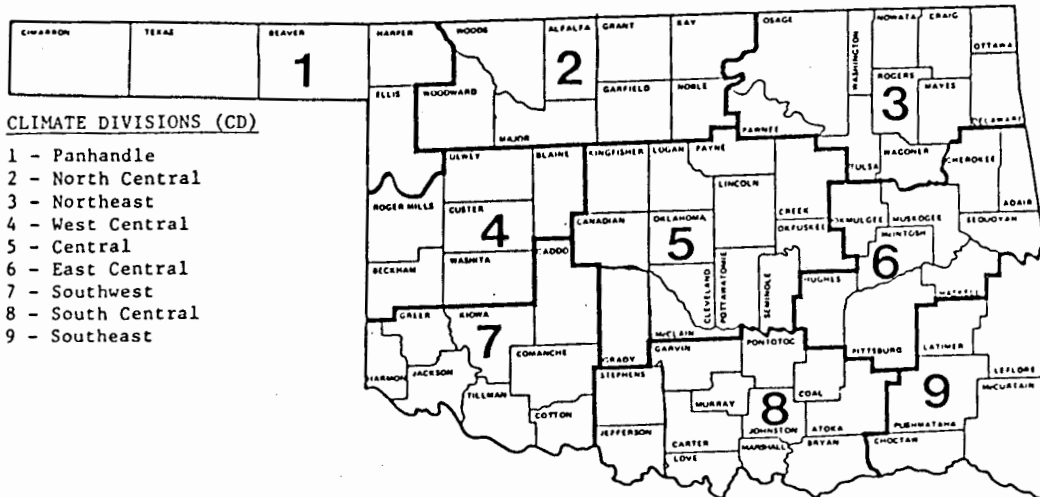

TABLE OF 1985/1986 SEPTEMBER COMPARISONS

Station	September Temperatures (F)		September Precipitation (in.)	
	1985	1986	1985	1986
Goodwell	67.6	70.5	7.273	.394
Lahoma	72.8	73.9	3.640	7.190

SEPTEMBER EXTREMES

Variable	Station	Division	Observation	Date
Minimum temperature (F)	Kenton	1	38	27
Maximum temperature (F)	Buffalo	1	101	17
Maximum 24-hour precipitation	Barnsdall	3	10.42"	29

EXPLANATION OF TABLES

Two kinds of tables appear in this summary. The first is a set of tables containing all reporting stations grouped by climate division. The figure above shows the locations of the climate divisions. Each table contains the following information for each station:

Station Name:

Station Identification Number: These are usually assigned by the National Climatic Data Center.

Climate Division: See the figure above.

Number of Temperature Observations: These are the actual number of temperature reports recorded at the station during the current month. Missing observations may result in artificially high or low mean monthly temperatures.

Deviation from Normal: The deviation of the observed mean monthly temperature from the monthly station normal. A positive value indicates the month was warmer than normal. A negative value indicates the month was cooler than normal. Normal monthly temperatures may be calculated by subtracting the deviation from the observed temperature.

Maximum Daily Maximum: The maximum daily maximum temperature observed during the current month and year and the day which it occurred.

Minimum Daily Minimum: The minimum daily minimum temperature observed during the current month and year and the day which it occurred.

Heating Degree Days: HDD are calculated each day of the month for which there is a temperature report and summed. They are a qualitative measure of how much heat was required to maintain an indoor temperature of 65 degrees. Missing observations may result in an artificially high or low value. For February 1984 HDD would be calculated as:

$$29 \sum_{i=1} (65 - TMAX_i + TMIN_i)/2$$

Deviation from Normal Heating Degree Days: A positive value indicates higher than normal heating requirements for the month as a whole. A negative value indicates lower than normal heating requirements for the month as a whole. Normal HDD may be calculated by subtracting the deviation from observed HDD.

Cooling Degree Days: CDD are calculated each day of the month for which there is a temperature report and summed. They are a proxy measure of how much cooling was required to maintain an indoor temperature of 65 degrees. Missing observations may result in an artificially high or low value. For June, CDD would be calculated as:

$$\sum_{i=1}^{30} ((TMAX_i + TMIN_i)/2 - 65)$$

Deviation from normal cooling Degree Days: A positive value indicates higher than normal cooling requirements for the month as a whole. A negative value indicates lower than normal cooling requirements for the month as a whole. Normal cooling degree days may be found by subtracting the deviation from the observed cooling degree days.

Total Precipitation: Often incorrectly referred to as mean precipitation, this value is the sum of all precipitation reported during the month at a station. If snow occurred, it is to be melted and its water equivalent recorded.

Number of Precipitation Observations: The number of days a rain or no-rain observation was reported. Missing observations frequently result in artificially low total precipitation values.

Deviation from Normal Precipitation: A positive value indicates more rain than normal was received. A negative value indicates less than was expected rainfall was received. Normal rainfall may be calculated by subtracting the deviation from monthly total.

Maximum 24-Hour Report and Day: The maximum amount of precipitation recorded during the station's 24-hour observation period for the current month and year and the day on which it was recorded.

The second set of tables contain similar information but are the average or extreme over all the stations reporting in each climate division.

EXPLANATION OF MAPS

To give a Statewide perspective, a series of maps is produced each month from the information contained in the station tables. Each map is calculated using between 50 and 200 observations. Only stations with complete monthly records are used. Each observation is put into one of three categories and assigned a plus (+), minus (-), or a dot (.). The minus is the lowest numeric category, the dot is the middle and the plus the highest numeric category. If a map location has no report, a value is estimated. Each map is accompanied by its own legend. The categories will vary from month to month throughout the year. The categories for the deviations from normal maps will always remain constant. This is to facilitate comparisons between months and across years.
